

APPARATUS AND METHOD FOR RESTARTING A SHARED VIRTUAL RESOURCE

ABSTRACT OF THE DISCLOSURE

An apparatus and method provide a protocol for communicating between an
5 operating system that owns a shared resource and other operating systems that use the
shared resource so that the operating systems that use the shared resource will not crash if
the operating system that owns the shared resource is restarted. Messages are defined that
allow handshaking between operating systems so that operating systems that share a
resource will realize the resource will be unavailable for some period of time, and that
10 allow resuming the sharing of the resource once the operating system that owns the
shared resource is restarted.
